CAP Protocol

Technology Deep Dive

Capability Aggregation Protocol

Scalable Distributed Coordination for Autonomous Systems

For Investors & Potential Acquirers

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Executive Summary

The Problem: Autonomous systems fail at scale due to $O(n^2)$ communication complexity

- Current approaches saturate at 10-20 nodes
- No human oversight in distributed networks
- Safety-critical systems need coordination guarantees

The Solution: CAP Protocol

- **95%+ bandwidth reduction** through hierarchical CRDT aggregation
- **Validated with 12-node ContainerLab** across 3 topology modes
- **Graduated human authority** for distributed autonomous control
- **Production-ready** with 330+ tests, 100% sync success

The State: 0-1 Startup

- Bootstrapped, no capital investment, fully liquid
- Rapidly evolving codebase with features, tests and laboratory experimentation
- Ontology -> Schema -> Code
- Abstractions for persistence, CRDT, and network functions

Part 1: The Problem Space

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

The Autonomous Systems Scalability Crisis

DIU COD Experience (2024)

- Defense Innovation Unit Collaborative Operations in Denied (COD) program
- **All-to-all communication saturates at 10-20 nodes**
- $O(n^2)$ message complexity becomes unbearable
- No solution for tactical edge networks (high latency, partitions, disconnectivity/DDIL)

Industry-Wide Challenge

- IoT swarms: Can't coordinate beyond small groups
- Robotics: Fleet coordination breaks down at scale
- Defense: Squad-level autonomy requires 12+ nodes minimum
- Cloud: Investments still tilting towards centralization
- Edge: Pushing cloud tech outward is failing

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Why Traditional Solutions Fail

Approach	Limitation	Example
Centralized Control	Single point of failure, no partition tolerance	Cloud orchestration
Broadcast Communication	$O(n^2)$ complexity, network saturation	Traditional UAV swarms
Consensus Algorithms	Requires majority, high latency, no partition tolerance	Paxos, Raft
Pure CRDTs	No coordination primitives, eventual consistency only	Automerge, Yjs

Gap: No system provides hierarchical coordination + partition tolerance + human authority

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

CRDTs Have a Problem

- CRDTs will never match raw TCP socket latency - Differential sync engines have inherent overhead for conflict-free replication vs direct message passing
- Convergence induces latency - The "eventual" in eventual consistency means sync propagation takes time, especially in multi-hop P2P topologies
- Value proposition is CAP theorem trade-offs - Accept higher latency for partition tolerance, eventual availability, and offline-first operation that traditional client-server can't provide
- Hierarchical P2P enables scale-out - While individual sync may be slower, architecture can handle network partitions and scale horizontally where centralized approaches fail

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Part 2: Core Innovations

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Innovation 1: Hierarchical Capability Composition

The Insight

Military squads naturally organize hierarchically:

- **Squad** (12 nodes) → **Platoon** (3 squads) → **Company** (3 platoons)
- Each level aggregates capabilities from subordinates
- O(n log n) message complexity vs O(n^2) for flat networks

Technical Approach

- **CRDTs for state**: Conflict-free replicated data types (Ditto SDK)
- **Composition rules**: Additive, emergent, redundant, constraint-based
- **Hierarchical aggregation**: Capabilities bubble up, commands flow down

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Composition Rule Patterns

```
// 1. Additive: Union of capabilities
squad.sensors = uav1.sensors ∪ uav2.sensors ∪ ugv1.sensors

// 2. Emergent: New capabilities from combinations
if squad.has(SENSOR_IR) && squad.has(SENSOR_RF) {
    squad.add(CAPABILITY_TARGET_CORRELATION)
}

// 3. Redundant: Threshold requirements
if squad.count(CAPABILITY_SURVEILLANCE) >= 2 {
    squad.add(CAPABILITY_PERSISTENT_ISR)
}

// 4. Constraint-based: Dependencies and exclusions
if squad.has(JAMMER_ACTIVE) {
    squad.remove(CAPABILITY_RADIO_RELAY)  // Mutual exclusion
}
```

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Validation: Hierarchical Aggregation Efficiency

ContainerLab Multi-Node Validation Results

Topology Mode	Nodes	Sync Success	Convergence Time	Bandwidth Reduction
Client-Server	12	100%	0.3s	96% vs broadcast
Hub-Spoke	12	100%	0.5s	95% vs broadcast
Dynamic Mesh	12	100%	0.8s	94% vs broadcast

Key Finding: Protocol maintains 100% sync success with hierarchical efficiency

- Real Docker networking with network constraints (latency, packet loss)
- Three topology modes validated
- Consistent bandwidth reduction across all modes

Source: ADR-015, VALIDATION_RESULTS.md

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Innovation 2: Graduated Human Authority Control

The Problem

Autonomous weapons systems need human oversight, but:

- Centralized control fails during network partitions
- Binary autonomous/manual modes are insufficient
- No audit trail for accountability

Five-Level Authority Taxonomy

```
FULL_AUTO ———→ No human approval required
SUPERVISED ——→ Human notified, can observe
COLLABORATIVE → Human works alongside system
MONITORED ———→ Human must explicitly approve actions
MANUAL ————→ Direct human control only
```

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Authority Control: Technical Implementation

Distributed Enforcement

- Authority level stored in CRDT (LWW-Register)
- Propagates through P2P mesh without centralized coordination
- **Hierarchical override**: Higher echelons can preempt local settings

Partition Tolerance

- Nodes operate autonomously during network splits
- Configurable timeout policies for human unavailability
- Deterministic conflict resolution when network reconverges

Audit Trail

- Cryptographic signatures on all decisions
- Immutable log of human interventions
- Compliance with DoD autonomy directives

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Innovation 3: Distributed Coordination Primitives

Beyond State Synchronization

CRDTs provide eventual consistency, but tactical operations need:

Requirement	Solution
Track deconfliction	Distributed claims registry
Fire control coordination	Priority-based conflict resolution
Formation control	Synchronized state transitions
Resource allocation	Temporal claims with timeouts
Safety zones	Spatial exclusion zone manager

Key Innovation: Coordination layer on top of CRDT sync that maintains safety during partitions

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Coordination Example: Target Deconfliction

```
// Platform 1 claims target
let claim = Claim {
    id: "claim-uuid-1",
    resource: Target::ID("enemy-tank-42"),
    claimant: "uav-alpha-1",
    priority: Priority::HIGH,
    expires_at: now() + 30.seconds(),
};

// Platform 2 also tries to engage same target
// Conflict resolver uses deterministic rules:
if claim2.priority > claim1.priority {
    grant_to(claim2);  // Higher priority wins
} else if claim2.priority == claim1.priority {
    grant_to(min(claim1.claimant, claim2.claimant));  // Lexical tiebreak
}

// Audit trail records both claims and resolution
audit_log.append(CoordinationEvent { claim1, claim2, resolution });
```

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Innovation 4: Multi-Layer Conflict Resolution

The Challenge

CRDT eventual consistency alone doesn't provide enough control for safety-critical systems

Three-Layer Approach

1. **Policy Engine (Write-time)**
   - Custom composition rules per capability type
   - Optimistic concurrency control (OCC)
   - Local enforcement before CRDT sync
2. **CRDT Semantics (Sync-time)**
   - LWW-Register for single-value fields (leader, position)
   - OR-Set for multi-value fields (membership)
   - Deterministic conflict resolution
3. **Application Logic (Read-time)**
   - Interpret CRDT state for tactical decisions
   - Safety checks and validation
   - Human-in-the-loop approval gates

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Part 3: Experimental Validation

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Validation Methodology

Four-Tier Validation Strategy

1. Unit & Integration Tests (Development)

- 330+ tests covering all protocol phases
- Property-based testing with `proptest`
- Fast feedback loop (<1s per test)

2. ContainerLab Multi-Node Validation (System)

- 12-24 node topologies with real Docker networking
- Network constraints: 10-500ms latency, 0-5% packet loss
- Four protocol modes tested across bandwidth constraints

3. Comprehensive Bandwidth Testing (E11)

- 16 test configurations (4 modes × 4 bandwidths)
- Bandwidths: 1Gbps, 100Mbps, 1Mbps, 256Kbps tactical radio
- Validates hierarchical aggregation efficiency (95%+ bandwidth reduction)

4. Traditional IoT Baseline Validation (E12)

- Empirical scaling study: 2-193 nodes
- Measured O(n^1.69) super-linear scaling in traditional architectures
- Single-machine testing up to 190+ nodes validated

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

ContainerLab Validation: Multi-Node Testing

Test Environment

- 12-24 containerized CAP Protocol nodes
- Ditto SDK 4.12+ for real CRDT synchronization
- Real Docker networking (not mocked/simulated)
- Network constraints via Linux traffic control (tc)

Key Results (E11 Comprehensive Bandwidth Testing)

- ✅ **16 test configurations** across 4 modes and 4 bandwidths
- ✅ **100% synchronization success** across all modes and bandwidths
- ✅ **Mode 4 Hierarchical**: 95.3% bandwidth reduction validated
- ✅ Protocol maintains functionality from gigabit ethernet to 256Kbps tactical radio
- ✅ P2P latency: 13-242ms avg across all bandwidth constraints
- ✅ Node discovery: <2s average
- ✅ Cell formation: <5s for 4-node cells

Source: test-bandwidth-suite-20251109-191705/BANDWIDTH_SUITE_REPORT.md

ContainerLab Network Topology Modes

Four Validation Topologies

1. **Client-Server** (Baseline)
   - All nodes connect to central server
   - Validates basic sync functionality
   - 12 nodes, latency: 13-38ms avg
2. **Hub-Spoke** (Hierarchical Realistic)
   - Mimics military squad hierarchy
   - Squad leaders as hubs, members as spokes
   - 12 nodes, latency: 16-29ms avg
3. **Dynamic Mesh** (Autonomous)
   - Nodes discover and form cells autonomously
   - Geographic self-organization
   - 12 nodes, latency: 14-21ms avg
4. **Hierarchical Aggregation** (Production)
   - 3 squads + platoon leader architecture
   - Squad leaders aggregate → Platoon leader aggregates
   - 24 nodes, latency: 133-242ms avg, **95.3% bandwidth reduction**

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Comprehensive Bandwidth Testing Results (E11)

Test Matrix: 4 Modes × 4 Bandwidths = 16 Configurations

Mode	1Gbps	100Mbps	1Mbps	256Kbps
Mode 1 (Client-Server)	15ms	13ms	38ms	14ms
Mode 2 (Hub-Spoke)	16ms	29ms	17ms	16ms
Mode 3 (Dynamic Mesh)	15ms	21ms	21ms	14ms
Mode 4 (Hierarchical)	206ms	133ms	243ms	212ms

Values shown: Average latency across all nodes

Key Findings:

- ✅ 100% synchronization success across all 16 configurations
- ✅ Mode 4 achieves 95.3% bandwidth reduction through hierarchical aggregation
- ✅ Protocol maintains functionality from gigabit to tactical radio bandwidths

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Traditional IoT Scaling Study (E12)

Empirical Baseline: Traditional Full-State Replication

Test Configuration:

- Architecture: Periodic full-state messages (5-second cycle)
- No differential sync, no CRDTs
- Scales: 2, 12, 24, 48, 96, 193 nodes
- Single-machine validation

Measured Scaling Behavior:

- **O(n^1.69) super-linear scaling complexity**
- 2 nodes: 0.06 MB/60s
- 96 nodes: 37.94 MB/60s
- 48x node increase → 682x traffic increase

Division-Scale Projection (1,536 nodes):

- **4.06 GB per minute** (67 MB/second sustained)
- Impractical for bandwidth-constrained tactical networks

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Single-Machine Testing Achievement (E12)

Infrastructure Validation

Docker Image Optimization:

- Original size: 11.8 GB
- Optimized size: 242 MB
- **98% size reduction** (48.8x smaller)

Scale Validated:

- Successfully tested 193-node topology on single machine
- Automated deployment, measurement, and teardown
- 5-second interval Docker stats collection with per-node granularity

Resource Efficiency:

- ~46 GB RAM for 193 containers
- vs ~2.3 TB unoptimized
- Enables rapid battalion-scale iteration before distributed deployment

Testing Framework Capabilities:

- ContainerLab-based automated topology deployment
- Comprehensive data processing and analysis pipeline
- Validated across 6 scales: 2, 12, 24, 48, 96, 193 nodes

© 2025 revolve. All Rights Reserved. | COMPETITION SENSITIVE

Protocol Migration Validation (ADR-012)

Protobuf Schema Migration

Objective: Migrate all core models to protobuf for extensibility and performance

Scope:

- Capability, Node, Cell, Zone models → protobuf
- Delta system removed (superseded by CRDT engines)
- Backward compatibility maintained

Results:

- ✅ All 330+ tests pass post-migration
- ✅ Zero API breaking changes
- ✅ Performance neutral or +5% (protobuf efficiency)
- ✅ Schema extensibility validated

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Systems Integration & Interoperability

The Integration Challenge

Problem: Modern military operations require integrating:

- **Greenfield systems**: New autonomous platforms (UGVs, UAVs, UUVs)
- **Brownfield systems**: Legacy C2, sensors, communications
- **Commercial robotics**: ROS-based drones, ground robots
- **Existing doctrine**: TTPs, command structures, approval workflows

CAP Solution: Protocol-agnostic integration layer that transforms at interfaces

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Greenfield vs Brownfield Integration

Greenfield Systems (New Autonomous Platforms)

Integration Approach: Native CAP protocol implementation

System Type	Integration Method	CAP Benefits
New UAVs/UGVs	Native CAP client	Full capability advertisement, autonomous cell formation
AI-enabled sensors	CAP SDK integration	Real-time data sharing, distributed coordination
Next-gen robotics	Built with CAP from day 1	Zero translation overhead, native CRDT sync

Example: New quadcopter swarm designed with CAP protocol

```
let cap_node = CapNode::new(NodeCapabilities {
    role: Role::Scout,
    sensors: vec![Sensor::EO, Sensor::IR],
    mobility: MobilityType::Aerial { max_altitude: 500 },
});
cap_node.advertise_capabilities();
cap_node.join_nearest_cell();
```

© 2025 revolve. All Rights Reserved. | COMPETITION SENSITIVE

Brownfield Integration Patterns

Legacy C2 Systems Integration

Challenge: Existing C2 systems use centralized architectures (ATAK, AFATDS, DCGS)

CAP Integration Strategy:

1. Gateway Translation Layer

```
Legacy C2 (ATAK/AFATDS)
    ↓ (Link16/VMF)
CAP Gateway Node
    ↓ (CRDT documents)
CAP Mesh Network (Autonomous Platforms)
```

Gateway Functions:

- Translates legacy messages → CAP capability documents
- Aggregates CAP state → C2 common operating picture
- Enforces authority levels (human-in-loop for legacy systems)
- Maintains audit trail for compliance

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

C2 Integration: Doctrine Preservation

Maintaining Existing TTPs

Key Principle: CAP adapts to doctrine, not vice versa

Command Authority Mapping

Legacy C2 Role	CAP Authority Level	Integration
Battalion Commander	MANUAL	All autonomous actions require explicit approval
Company Commander	MONITORED	Approval required for fires, movement
Platoon Leader	COLLABORATIVE	Collaborate on target selection
Squad Leader	SUPERVISED	Observe autonomous recommendations
Team Member	SUPERVISED	Observe sensor feeds, status

Implementation:

- CAP gateway receives commander's authority level setting
- Propagates through CRDT to all autonomous platforms
- Platforms enforce locally during network partitions
- Audit trail flows back to C2 for accountability

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Commercial Robotics Integration (ROS/ROS2)

ROS-to-CAP Bridge

Problem: Commercial drones/robots use Robot Operating System (ROS)

- Topic-based pub/sub messaging
- Centralized roscore (single point of failure)
- No native support for partitioned operations

CAP Bridge Architecture:

```
ROS Node (Drone autopilot)
    ↓ /mavros topics
ROS-CAP Bridge
    ↓ Capability documents
CAP Mesh Network
```

Bridge Functions

Outbound (ROS → CAP):

- `/mavros/state` → CAP Node heartbeat
- `/mavros/global_position` → CAP Zone awareness
- `/camera/image` → CAP Sensor data capability

Inbound (CAP → ROS):

- CAP coordination commands → `/mavros/setpoint_position`
- CAP authority level → Flight controller safety constraints
- CAP cell membership → ROS namespace allocation

© 2025 revolve. All Rights Reserved. | COMPETITION SENSITIVE

Interface Transformation Strategy

Multi-Layer Integration

CAP enables transformation at **every interface layer**:

1. Data Layer

- **Transform**: Sensor feeds → Capability documents
- **Benefit**: Heterogeneous sensors appear uniform to consumers

2. Coordination Layer

- **Transform**: C2 orders → Distributed claims/coordination primitives
- **Benefit**: Centralized commands work in partitioned networks

3. Authority Layer

- **Transform**: Doctrine-based ROE → CAP authority levels
- **Benefit**: Human oversight preserved across legacy/modern systems

4. Network Layer

- **Transform**: Link16/SATCOM → P2P CRDT mesh
- **Benefit**: Protocols interoperate without central infrastructure

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Real-World Integration Example

Scenario: Integrate Commercial DJI Drones into Army Squad

Existing Setup:

- Squad uses ATAK on Android tablets (C2)
- DJI drones run proprietary firmware
- No coordination between drones and ground units

With CAP Integration:

```
ATAK Tablet  (Legacy C2)
      │ TAK Protocol
      ▼
  Gateway  (Raspberry Pi w/ CAP SDK)
      │ CRDT Mesh
      ▼
  UGV      ──────►  DJI UAV  (w/ CAP bridge)
      │                 │
      ▼                 ▼
  Soldier          Soldier  (w/ CAP-enabled radios)
```

Integration Points:

1. ATAK → CAP Gateway: TAK protocol translated to CAP documents
2. DJI → CAP Bridge: DJI SDK calls wrapped in CAP client
3. Radios: Native CAP protocol (greenfield)

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Result: Commercial drones coordinate with military units using existing C2

Integration Benefits Summary

Interoperability Advantages

Benefit	Impact
Doctrine Preservation	Existing TTPs, command structures, ROE remain unchanged
Gradual Adoption	Mix legacy and modern systems during transition
Vendor Neutrality	Any drone/robot can integrate (not locked to single vendor)
Future-Proof	New platforms integrate without rearchitecting C2
Partition Tolerance	Systems coordinate even when gateway offline

Economic Advantages

- **Reuse existing C2 investments**: No need to replace ATAK, AFATDS, etc.
- **Commercial robotics leverage**: Use $1K DJI drones, not $100K mil-spec
- **Incremental deployment**: Start with gateway + few platforms, scale up
- **Training reduction**: Soldiers use familiar C2 interfaces

CRDT Types & Usage

CRDT Type	Use Case	Example
G-Set (Grow-only Set)	Static capabilities	`sensors: {IR, RF, GPS}`
OR-Set (Observed-Remove Set)	Dynamic membership	`cell_members: {uav1, uav2, ugv1}`
LWW-Register (Last-Write-Wins)	Single-value fields	`leader: "uav-alpha-1"`, `position: (lat, lon)`
PN-Counter (Positive-Negative)	Numeric values	`fuel_level: 75`, `ammo_count: 120`

Key Property: All CRDTs are commutative, associative, and idempotent
→ Eventual consistency guaranteed regardless of message order or network partitions

Code Quality: Rust safety guarantees, 330+ tests, comprehensive documentation

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Technology Stack

Layer	Technology	Rationale
Language	Rust	Memory safety, performance, embedded-ready
CRDT Engine	Ditto SDK 4.12+	P2P mesh, observer-based sync, production-ready
Schema	Protocol Buffers	Efficient serialization, extensibility, cross-language
Testing	Rust test + proptest	Unit, integration, E2E with real CRDT mesh
Simulation	ContainerLab	Multi-node validation with real Docker networking
Build	Cargo + Makefile	Fast builds, reproducible, CI/CD friendly

Key Decision: Ditto SDK chosen over Automerge/Iroh for production-readiness and P2P mesh support (ADR-011)

Part 5: Intellectual Property

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Patent Strategy

Two Provisional Patent Applications

1. Hierarchical Capability Composition (45 pages)

Innovation: CRDT-based hierarchical aggregation for autonomous systems

Key Claims:

- Additive, emergent, redundant, constraint-based composition patterns
- O(n log n) message complexity through hierarchical aggregation
- Partition-tolerant capability composition with eventual consistency

2. Graduated Human Authority Control (42 pages)

Innovation: Five-level distributed human oversight system

Key Claims:

- Five-level authority taxonomy (FULL_AUTO → MANUAL)
- Distributed enforcement via CRDT mesh without centralization
- Cryptographic audit trail for accountability
- Partition-tolerant with configurable timeout policies

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Patent Pledge: Defensive Use Only

Commitment to Open Innovation

Who is Protected:

- ✅ Government and defense organizations
- ✅ Academic and research institutions
- ✅ Open-source contributors
- ✅ Non-commercial use

Intent: Defensive protection against competitors/patent trolls, not offensive assertion

Precedent: Google, Red Hat, Tesla use this approach

- Patents for defense and M&A value
- Pledge for openness and collaboration

Full strategy: docs/patents/

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

IP Documentation

Comprehensive Technical Documentation

16 Architecture Decision Records (ADRs):

- Every major technical decision documented with rationale
- Trade-offs analyzed, alternatives considered
- References to validation results

Examples:

- ADR-001: CAP Protocol POC (core architecture)
- ADR-014: Distributed Coordination Primitives (novel contribution)
- ADR-015: Experimental Validation (scientific methodology)

Value for Acquirer: Complete understanding of design decisions and IP boundaries

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Part 6: Market Opportunity

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Primary Market: Defense & Tactical Edge

Total Addressable Market (TAM)

Segment	Market Size	Growth	CAP Fit
DoD Autonomous Systems	$5.4B (2024)	12% CAGR	★★★ Perfect
UAV/UGV Swarms	$2.1B (2024)	18% CAGR	★★★ Perfect
Tactical Edge AI	$1.8B (2024)	22% CAGR	★★★ Perfect
C4ISR Modernization	$12.3B (2024)	8% CAGR	★★ Strong

Target Customers: USAF, Army, SOCOM, DARPA, DIU, NATO allies

Key Drivers:

- DIU COD experience shows need for scalable coordination
- DoD autonomy directives require human oversight (Directive 3000.09)
- JADC2 initiatives need distributed coordination at tactical edge

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Secondary Market: Commercial Applications

High-Value Adjacent Markets

IoT & Edge Computing ($47B by 2027)

- Smart city infrastructure coordination
- Industrial IoT fleet management
- Distributed sensor networks

Robotics & Automation ($74B by 2026)

- Warehouse robot coordination (Amazon, Ocado)
- Autonomous vehicle fleets (logistics, delivery)
- Agricultural robot swarms

Satellite Constellations ($23B by 2030)

- LEO mega-constellation coordination (Starlink, OneWeb)
- Formation flying and collision avoidance
- Distributed ground station networks

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Competitive Landscape

Direct Competitors (Distributed Coordination)

Competitor	Approach	Limitation
DIU COD	$O(n^2)$ broadcast	Saturates at 10-20 nodes
ROS 2 DDS	Pub/Sub broadcast	No hierarchical coordination
Swarm-level autonomy (academic)	Consensus-based	No partition tolerance
Proprietary defense systems	Centralized control	Single point of failure

Indirect Competitors (CRDT/Sync)

Product	Use Case	Missing in CAP
Automerge/Yjs	Document collaboration	No coordination primitives, no hierarchy
Conflict-free replicated data	General state sync	No tactical operations support

Competitive Advantage: Only solution combining hierarchy + partition tolerance + human authority + coordination primitives

Go-to-Market Strategy

Phase 1: GOTS/SBIR (Years 1-2)

- Government Off-The-Shelf (GOTS) positioning
- SBIR Phase I/II funding ($1M-$3M)
- Pilot programs with USAF, Army, SOCOM
- NATO standardization efforts

Phase 2: Prime Integrator Partnerships (Years 2-4)

- License to defense primes (Northrop, Lockheed, RTX)
- Integration into existing platforms (UAVs, C2 systems)
- Dual-use commercial applications (IoT, robotics)

Phase 3: Platform Play (Years 4+)

- CAP-as-a-Service for edge computing
- Developer ecosystem and tooling
- Industry standards and reference implementations

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Part 7: Development Roadmap

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Current Status: Production-Ready

Completed (100%)

✅ **Core Protocol Implementation**

- Three-phase protocol (discovery, cell formation, hierarchical operations)
- CRDT-based state synchronization (Ditto SDK)
- Hierarchical capability composition with 4 rule patterns

✅ **Advanced Features**

- Graduated human authority control (5 levels)
- Policy engine with optimistic concurrency control
- TTL & data lifecycle management
- Protobuf schema migration for extensibility

✅ **Validation & Testing**

- 330+ tests (unit, integration, E2E)
- ContainerLab 12-node validation (100% success rate)
- ContainerLab multi-node validation (12 nodes, 3 topology modes)

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Roadmap: Next 12 Months

Q1 2025: Hardening & Security

- [ ] Cryptographic identity and authentication
- [ ] End-to-end encryption for sensitive data
- [ ] Security audit and penetration testing
- [ ] FIPS 140-2 compliance investigation

Q2 2025: Distributed Coordination Primitives

- [ ] Complete ADR-014 implementation (claims registry)
- [ ] Spatial exclusion zones for safety
- [ ] Time-bounded operations with temporal constraints
- [ ] Audit trail with cryptographic signatures

Q3 2025: Multi-Backend Transport

- [ ] Automerge/Iroh backend implementation
- [ ] Transport abstraction layer finalization
- [ ] Benchmark Ditto vs Automerge performance
- [ ] Multi-language bindings (Python, C++ via FFI)

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Roadmap: 12-24 Months

Q4 2025: Production Deployment

- [ ] Government customer pilot program
- [ ] Integration with existing C2 systems
- [ ] Field testing with real autonomous platforms
- [ ] Documentation for operators and integrators

2026: Ecosystem Development

- [ ] Reference implementations for common use cases
- [ ] Developer SDK and tooling
- [ ] Visualization and monitoring tools
- [ ] Training and certification programs

2026+: Advanced Features

- [ ] Machine learning for capability prediction
- [ ] Adaptive topology optimization
- [ ] Cross-domain coordination (air-ground-sea)
- [ ] Embedded hardware ports (ARM, RISC-V)

Part 8: Risk Assessment

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Technical Risks

Risk	Probability	Impact	Mitigation
CRDT performance at large scale	Medium	High	ContainerLab validates 12-node deployment, Ditto tested to 10K+ nodes by vendor
Network partition duration	Low	Medium	Configurable timeouts, deterministic reconvergence tested
Security vulnerabilities	Medium	High	Rust memory safety, security audit planned Q1 2025
Ditto SDK vendor lock-in	Low	Medium	Transport abstraction (ADR-011), Automerge backend planned

Overall Technical Risk: Low - Core protocol validated, production-ready codebase

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Market & Business Risks

Risk	Probability	Impact	Mitigation
Government budget cuts	Medium	High	Dual-use commercial applications, NATO allies
Competitor solution emerges	Low	High	Patents + 2-year head start, proven at scale
Integration complexity	Medium	Medium	Reference implementations, professional services
Regulatory/export control	Low	Medium	GOTS strategy, open-source with patent pledge

Overall Market Risk: Medium - Defense market cyclicality, but strong dual-use story

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

IP & Legal Risks

Risk	Probability	Impact	Mitigation
Prior art invalidates patents	Low	Medium	Provisional applications cite DIU COD, novel claims focus on CAP-specific innovations
Open-source licensing issues	Very Low	Low	Apache-2.0/MIT dual-license, all dependencies permissive
Patent assertion by competitor	Low	Medium	Defensive patent strategy, prior art documentation

Overall IP Risk: Low - Strong patent position, defensive use pledge

Part 9: Investment Thesis

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Why CAP Protocol Wins

1. Proven Technology

- ✅ **100% sync success** under realistic network constraints
- ✅ **12-node ContainerLab** validation across 3 topology modes
- ✅ **95%+ bandwidth reduction** confirmed experimentally
- ✅ **330+ tests** including comprehensive E2E validation

2. Novel IP

- 🔒 **2 provisional patents** covering core innovations
- 🔒 **16 ADRs** documenting technical decisions and IP boundaries
- 🔒 **First to solve** hierarchy + partition tolerance + human authority

3. Validated Performance

- ✅ **100% sync success** under realistic network constraints
- ✅ **12-node ContainerLab** deployment validated across 3 topology modes
- ✅ **95%+ bandwidth reduction** vs traditional broadcast approaches

4. Market Timing

- 📈 DIU COD failure creates urgent need (2024)
- 📈 DoD autonomy directives require human oversight
- 📈 JADC2 initiatives need distributed coordination

Acquisition Value Proposition

For Defense Primes (Northrop, Lockheed, RTX)

- **Technology Gap**: No internal solution for scalable autonomous coordination
- **Time to Market**: 2+ years ahead of building in-house
- **IP Portfolio**: Patents strengthen competitive position
- **Integration**: Drop-in replacement for existing $O(n^2)$ approaches

For Platform Companies (Google, Amazon, Microsoft)

- **Cloud Edge**: CAP enables distributed edge computing at scale
- **IoT Portfolio**: Solves coordination problem for IoT/robotics products
- **AI/ML Integration**: Foundation for multi-agent AI systems
- **Strategic**: Defensible technology moat via patents

For VC-Backed Autonomy Startups

- **Acqui-hire**: Experienced team with proven technical chops
- **Technology Acceleration**: Skip 2 years of R&D
- **Customer Traction**: Government validation via GOTS/SBIR

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Financial Projections (Illustrative)

Revenue Potential (Year 5, assuming GOTS + licensing)

Revenue Stream	Conservative	Aggressive	Notes
Government Contracts	$5M	$15M	SBIR Phase III, production contracts
Prime Integrator Licensing	$3M	$10M	3-5 primes @ $1M-$2M/year
Commercial Licensing	$1M	$5M	IoT, robotics, cloud edge
Professional Services	$1M	$3M	Integration, training, support
Total Revenue	**$10M**	**$33M**	

Valuation Multiple: 8-12x revenue (defense software SaaS comparable)
Implied Valuation (Year 5): $80M - $400M

Note: Projections are illustrative and depend on execution, market adoption, and strategic partnerships

Part 10: Ask & Next Steps

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Investment Ask

Seed Round: $2M - $3M

Use of Funds:

- **Engineering (60%)**: Security hardening, distributed coordination primitives, multi-backend
- **Go-to-Market (25%)**: SBIR applications, pilot programs, defense industry partnerships
- **Operations (15%)**: Legal (patent prosecution), infrastructure, administrative

Milestones:

- ✅ Security audit and FIPS compliance (Q1 2025)
- ✅ SBIR Phase I award ($250K-$300K) (Q2 2025)
- ✅ First pilot program with government customer (Q3 2025)
- ✅ Prime integrator partnership or licensing deal (Q4 2025)

Exit Strategy: Acquisition by defense prime or platform company within 3-5 years

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Acquisition Scenarios

Strategic Acquirer Profile

Tier 1: Defense Primes ($50M - $150M)

- Northrop Grumman, Lockheed Martin, Raytheon
- **Rationale**: Fills technology gap in autonomous systems portfolio
- **Timing**: After SBIR Phase II or first production contract

Tier 2: Platform Companies ($30M - $80M)

- Google (Cloud Edge), Amazon (IoT/Robotics), Microsoft (Azure Edge)
- **Rationale**: Enables distributed edge computing strategy
- **Timing**: After commercial traction in IoT/robotics

Tier 3: Autonomy Startups ($20M - $50M)

- Shield AI, Anduril, Skydio (autonomy-focused)
- **Rationale**: Accelerates coordination technology roadmap
- **Timing**: Earlier acquisition for team + technology

Due Diligence Materials

Available Now

✅ **Technical Documentation**: 16 ADRs, IP_OVERVIEW.md, VALIDATION_RESULTS.md
✅ **Code Repository**: Full source code, 330+ tests, CI/CD pipeline
✅ **Patent Applications**: 2 provisional applications (87 pages), patent strategy
✅ **Validation Data**: ContainerLab test logs, network topology validation results
✅ **Roadmap**: 24-month development plan with milestones

Next Steps for Interested Parties

1. **Technical Deep Dive** (Week 1-2): Engineering team review of codebase and validation
2. **IP Review** (Week 2-3): Patent attorney review of provisional applications
3. **Market Validation** (Week 3-4): Customer discovery with potential government buyers
4. **Term Sheet** (Week 4-6): Investment or acquisition proposal

Appendix: Technical Deep Dives

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Appendix A: CRDT Fundamentals

What are CRDTs?

Conflict-free Replicated Data Types - data structures that guarantee eventual consistency without coordination

Key Properties

1. **Commutative**: Order of operations doesn't matter
2. **Associative**: Grouping of operations doesn't matter
3. **Idempotent**: Applying same operation multiple times has same effect as once

Why CRDTs for CAP?

- ✅ No centralized coordination required
- ✅ Partition tolerance built-in
- ✅ Provably convergent (mathematical guarantees)
- ✅ Production-ready implementations (Ditto, Automerge)

CAP Innovation: CRDTs alone aren't enough - we add hierarchy, human authority, and coordination primitives

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Appendix B: Ditto SDK Integration

Why Ditto over Automerge/Iroh?

Feature	Ditto	Automerge	Iroh
Production-ready	✅ 4.12+ stable	⚠️ Still evolving	⚠️ Early stage
P2P mesh networking	✅ Built-in	❌ BYO transport	✅ Built-in
Observer pattern	✅ Event-driven	❌ Polling required	⚠️ Limited
Platform support	✅ iOS, Android, embedded	✅ Web-focused	✅ Rust-focused
Commercial support	✅ Enterprise SLA	❌ Community	❌ Community

Decision: Ditto for initial implementation, abstraction layer for future flexibility (ADR-011)

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Appendix C: Observer-Based Sync Pattern

Why Not Polling?

```
// ❌ BAD: Polling (adds latency, wastes CPU)
loop {
    let state = store.query("SELECT * FROM nodes");
    if state_changed(&state) {
        handle_update(state);
    }
    sleep(100ms);  // Arbitrary delay
}

// ✅ GOOD: Observer pattern (event-driven, instant)
let (tx, rx) = mpsc::unbounded_channel();
let observer = store.register_observer_v2(&query, move |result| {
    tx.send(Event::StateChanged(result));  // Instant notification
});

// React immediately to changes
while let Some(event) = rx.recv().await {
    handle_update(event);  // <1ms latency
}
```

Impact: Sub-millisecond propagation latency vs 100ms+ with polling

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Appendix D: Testing Philosophy

Test Pyramid for Distributed Systems

```
        ┌──────────┐
        │   E2E    │   10% effort, 100% mission assurance
        │ (Real    │   - Real Ditto instances
        │  CRDT)   │   - Observer-based validation
        └──────────┘   - Isolated test sessions

      ┌──────────────┐
      │Integration   │ 20% effort
      │   Tests      │ - Component interaction
      │              │ - Mock CRDT for speed
      └──────────────┘

    ┌────────────────┐
    │  Unit Tests    │ 70% effort
    │  (Business     │ - Fast (<1ms per test)
    │   Logic)       │ - Deterministic
    └────────────────┘
```

Critical: E2E tests with real Ditto instances validate distributed CRDT mesh behavior

→ Unit tests can't catch distributed race conditions or partition scenarios

Appendix E: Performance Benchmarks

Measured Performance (12-Node ContainerLab)

Metric	Measured	Target	Status
Node state update	4.2ms (p99)	<10ms	✅
Capability composition	8.7ms (p99)	<20ms	✅
Leader election	3.8s (avg)	<5s	✅
Discovery (12 nodes)	18s (avg)	<60s	✅
CRDT convergence	0.3s (avg)	<1s	✅
Command propagation	67ms/level (avg)	<100ms	✅

All performance targets met in realistic network conditions (100ms latency, 1% packet loss)

Appendix F: Comparison to Academic State-of-Art

Related Work

Paper/System	Year	Approach	Limitation vs CAP
Raft (Ongaro, 2014)	2014	Consensus	No partition tolerance, requires majority
CRDTs (Shapiro, 2011)	2011	Eventual consistency	No coordination primitives, no hierarchy
Swarm robotics (various)	2015+	Consensus/gossip	No human authority, limited scale
JADC2 architectures (DoD)	2020+	Centralized	Single point of failure

CAP Contribution: First to combine hierarchical CRDT aggregation + human authority + coordination primitives + partition tolerance

Publications: Paper in preparation for IEEE Transactions on Robotics (target: Q2 2025)

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Appendix G: Deployment Scenarios

Scenario 1: Tactical UAV Squad (12 Nodes)

- 4 ISR UAVs (quadcopters, 30min endurance)
- 4 Strike UAVs (fixed-wing, 60min endurance)
- 2 UGVs (ground surveillance, persistent)
- 1 Ground Control Station (human operator)
- 1 C2 Relay (network backbone)

Network: Tactical radios (900MHz), 100ms latency, 1% packet loss
Authority Level: MONITORED (human approval for strikes)
Validated: ✅ 100% sync success in ContainerLab hub-spoke topology

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Scenario 2: IoT Smart Building (Scaled Deployment)

- Multiple 12-node hierarchical groups
- HVAC, lighting, security, access control
- Squad-level coordination within building zones

Network: WiFi mesh, 50ms latency, <0.1% packet loss

Authority Level: FULL_AUTO (no human approval needed)

Scalability: ContainerLab validates building block, hierarchical composition enables scale

© 2025 revolve. All Rights Reserved. | **COMPETITION SENSITIVE**

Scenario 3: Warehouse Robot Fleet (Scaled Deployment)

- Multiple 12-node robot squads
- Autonomous mobile robots (AMRs)
- Hierarchical coordination across warehouse zones

Network: 5GHz WiFi, 20ms latency, <0.1% packet loss
Authority Level: SUPERVISED (human notified, can intervene)
Scalability: Client-server topology validates basic coordination
